

SOFT-TISSUE CASE 34. PRESENTATION

A 55-year-old woman with no significant medical history was admitted to hospital with a 3-day episode of severe pain in the right upper abdominal quadrant. She denied any postprandial pain. For 2 months she had been treated for an upper respiratory tract infection with

cough by a local general practitioner.

On examination there was a vague tender mass in the right upper quadrant. There was no rebound tenderness. She was afebrile and her leukocyte count was $14 \times 10^9/\text{L}$. Her hemoglobin level was 117 g/L and results of liver function tests were nor-

mal. Ultrasonography of the biliary tree was suboptimal because of numerous bowel gas shadows. Magnetic resonance imaging of the upper abdomen was done (Figs. 1 and 2).

What would be your diagnosis?

For the answer and discussion see page 306.
